

VENTURI MIXERS FLOMIXERS SERIES

FEATURES

- Construction: compact in aluminium
- Max. air pressure: 145 mbar
- Max. mixture pressure: 56 mbar
- Wide modulating range.

APPLICATIONS

- Adequate to all burners.

INSTALLATION

- Use of flange connections eliminating unions in gas and air lines.
- Easy accessibility of entrainment insert for inspection, cleaning or changing capacity without disconnecting gas or air lines.
- Universal type gas adjuster-good for any kind of gas.
- Ample pressure test plugs to facilitate checking air pressure, gas suction and mixture pressure.
- Output mixture pipes to the FLOMIXERS with inserts bigger than 54 must be expanded to diam.6" (DN 150) before connecting to the general manifold.
- It is advisable to size mixture pipes correctly; pressure drops should not exceed 2.5 mbar.

F230101

DESCRIPTION

Flomixers are proportional mixing devices that utilize the energy of a stream of air to suction the combustible gas and to deliver the mixture (Venturi effect).

Referring to the sketch (fig. no. 1), Flomixer operation may be described as follows: air at any available pressure (P1) passes through the air sleeve "A" into the air jet "B", where it develops the maximum possible velocity. This stream of air moving at high speed creates a suction (P2) of about -5 mbar in the chamber "C". This strong suction draws gas from the zero pressure chamber "E"

through the gas adjuster "D", chamber "C" and gas ports "F" into the space around the air stream in insert "G". The mixture flows into the pressure conversion chamber "H" (P3) and is delivered from the outlet flange to the manifold piping and burners. The quantity of gas entrained is obviously proportional to the suction effect which varies according to the air inlet pressure.

The flomixer responds to all of the varying forces exerted upon it, (air and gas pressures, piping, effective burner areas, etc.). Since the capacity is in equilibrium with other variables, any change in one will cause a corresponding change in the others. Therefore the air and gas ratio stays constantly balanced if the three pressures, that is air (P1), gas (P2) and mixture (P3) pressures and the three sections, that is air (A1), gas (A2) and mixture (A3) stay adequately balanced among them (fig.2).

Flomixer capacity ratings are based on correct burners (A3) to air jet area (A1) relations. In order to secure satisfactory performance from combinations of burners and flomixers, it is important that they be correctly matched in capacity or have the correct relationship between the flomixer air jet and the total effective burner port area.

The selection of the proper flomixer depending on the sections may be very difficult unless the true discharge coefficient is known. This coefficient stands for the capacity of the burner which acts as an orifice, because the gas fuel flowing through it has a pressure drop at that point.

The adjustment of the capacity in systems working with a flomixer may be done by adjusting only the air pressure; as a matter of fact the gas inspired depends on the program set for the gas adjuster (A2). When the air jet area (A1) is correctly sized in relation to the burners area (A3), a good, stable negative pressure P2 is always

obtained. If the mixture pressure P3 is too high, a positive pressure occurs in P2 and therefore the mixer does not work correctly any longer.

Every pressure drop between the mixer outlet and the burners entails an increase in pressure P3. For this reason the mixture piping size must be adequate to the capacity and have as few restrictions, joints or elbows as possible so that pressure losses downstream of the mixer are less than 2.5 mbar. Flomixers may be used to obtain any mixture with 75% to 100% aeration.

Flomixers are characterized by complete flexibility of right and left - up or down installation without special parts, so all parts in each series are interchangeable, easy accessibility of entrainment insert for inspection, cleaning or changing capacity without disconnecting gas or air lines. The table in the following pages shows the maximum insert range for each series. It is recommended, however, that only the insert sizes specified in the capacity table I be used. If larger inserts are used, excessive velocity and friction pressure losses in the mixture piping may occur.

A correctly sized zero regulator may be mounted. When flomixers are used in groups and utilize a single zero regulator it is essential, for accurate air-gas proportioning, that the gas pressure at the adjuster inlets be held at zero.

This requires not only an accurate zero regulator but proper sizing of the gas lines between regulator and mixers.

N.B. For further information on Zero Regulators, consult technical bulletin E5101.

FLOMIXER SELECTION

Use one of the following methods:

- CAPACITY BASIS - 100% AERATION.

For applications requiring a complete air-gas mixture, that is 100% primary air. Knowing the desired capacity (kW) and the type of fuel gas, the flomixer is selected directly from Table I under the air pressure column. If the correct air pressure falls between listed air pressures, the selection procedure is changed as follows:

$$\text{Capacity} \times \frac{\sqrt{\text{Air pressure (Table)}}}{\sqrt{\text{Air pressure (actual)}}} = \text{Selection capacity}$$

- CAPACITY BASIS - LESS THAN 100% AERATION.

For applications where less than 100% primary air mixtures are required. Knowing the desired kW capacity and percentage aeration, a new flomixer "selection capacity" is computed. Multiplying the kW capacity by the aeration percentage gives the new figure (Multiplier for 80% aeration is 0.8). Using this new figure, the flomixer is selected from Table I under the air pressure column.

- BURNER AREA BASIS.

Knowing the number, size, and type of burners required, determine the total port area and correct this area for burner discharge coefficient (using Table II, divide burner area by discharge coefficient). When burners and flomixers are matched on the area relationship basis, capacities shown in the flomixer table are for complete air-gas mixtures. For operation at other air-gas ratios, the corrected burner area should be multiplied by the aeration percentage before selecting the flomixers.

This new "burner area" is then used to select the proper flomixer from Table I under the proper air pressure and fuel gas columns.

- CAPACITY BASIS.

Low mixture pressures. For the selection of flomixers to be used with multi-port, Pyroline or ribbon type burners where the maximum burner mixture pressure must be considerably less than shown in the flomixer table. Most ribbon pipe burners are figured for a mixture pressure of 0.5 mbar but the newer piloted types can handle mixtures up to 1.5 mbar. Operating against these lower mixture pressures, flomixer capacities are higher than listed in Table I.

Knowing the air pressure, type of gas and total kW to be supplied to one or more burners, the actual burner capacity is re-figured to get a new "selection capacity". Under the proper air pressure column of Table IV, select the desired operating mixture pressure. The figure to the right under column (J) is the "capacity multiplier" and is used as follows:

$$\frac{\text{Burner capacity}}{\text{Capacity multiplier "J"}} = \text{Selection capacity}$$

Corrections for air-gas ratio should be applied to the "selection capacity" before selecting the flomixer.

The "selection capacity", which is always smaller than the original "burner capacity", is used to select the flomixer under the proper air pressure and gas columns in the flomixer selection Table I.

THE FLOMIXER, BECAUSE OF ITS ADVANCED DESIGN, WILL GIVE SUPERIOR PERFORMANCE IF USED WITHIN THE LIMITS OF NORMAL OPERATION.

POSSIBLE ASSEMBLED GROUPS

2301 - SERIES NO. 1

F2301104

It is the basic series and includes:

- Mixer body
- Cone-shaped insert (screw inside the body)
- Air inlet and mixture outlet flanges
- Gas adjuster (series GA) welded to the mixer body through ESA-PYRONICS standard flanges.

2303 - SERIES NO. 3

F2301106

As compared to series no. 1, a straight air sleeve (standard ESA-PYRONICS) with pressure plug is placed between the mixer body and the air inlet flange.

2302 - SERIES NO. 2

F2301105

As compared to series no. 1, the air inlet flange is replaced by a butterfly valve having one flanged side (standard ESA-PYRONICS) and one threaded side GAS.

2304 - SERIES NO. 4

F2301107

As compared to series no. 2, a straight air sleeve (standard ESA-PYRONICS) with pressure plug is placed between the mixer body and the butterfly valve.

For these 4 assemblies it is easy to deduct some data concerning the equipment from the abbreviations. In the catalog number of the flomixers the first group of figures stands for the diameter of the air inlet (the same of the mixture outlet) and the diameter of the gas inlet respectively (see below table).

After the first hyphen the number of the assembly of the flomixer comes. The type of working to be executed on the cone-shaped insert (according to the flow) is specified by the number after the second hyphen.

TABLE II - CORRECTION FACTORS FOR VARIOUS TYPES OF BURNERS

Type of burner	Pepper box or multiple port burners AGF-KEMP-SELAS	Flame retaining, or piloted burners, blast types BRYANT-MAXON-N.A. ECLIPSE	Annular or single port type round or flat nosed tunnel burners BRYANT - N.A.-SURFAE NAT'L	Venturi type steel tunnel burners ECLIPSE
Approximate coefficient of discharge	0.45 ÷ 0.65	0.65 ÷ 0.75	0.75 ÷ 0.95	1.00 ÷ 1.20
Factor	2.0 ÷ 1.4	1.4 ÷ 1.2	1.2 ÷ 1.0	0.9 ÷ 0.75

TABLE III - MIXTURE PRESSURE DEVELOPED BY FLOMIXERS AT VARIOUS AIR PRESSURES

Air pressure mbar	8.8	17.6	26.4	35.1	44	52.7	61.5	70.3	79	87.9	96.7	105.5	114.2	123	131.8	140.6
